Overview NetScaler VPX

Citrix NetScaler is an all-in-one application delivery controller that makes applications run up to five times better, reduces application ownership costs, optimizes the user experience and ensures that applications are always available by using:

- Advanced L4-7 load balancing and traffic management
- Proven application acceleration such as HTTP compression and caching
- An integrated application firewall for application security
- Server offloading to significantly reduce costs and consolidate servers

As an undisputed leader of service and application delivery, Citrix NetScaler is deployed in thousands of networks around the world to optimize, secure and control the delivery of all enterprise and cloud services. Deployed directly in front of web and database servers, NetScaler combines high-speed load balancing and content switching, http compression, content caching, SSL acceleration, application flow visibility and a powerful application firewall into an integrated, easy-to-use platform. Meeting SLAs is greatly simplified with end-to-end monitoring that transforms network data into actionable business intelligence. NetScaler allows policies to be defined and managed using a simple declarative policy engine with no programming expertise required.

Overview NetScaler in Amazon AWS

Support for the Citrix® NetScaler VPX within Amazon Web Services (AWS) is available beginning with version 10.5-61.11. NetScaler VPX is available as an Amazon Machine Image (AMI) in AWS marketplace. NetScaler VPX on AWS enables customers to leverage AWS Cloud computing capabilities and use NetScaler load balancing and traffic management features for their business needs. NetScaler on AWS supports all the traffic management features of a physical NetScaler appliance. NetScaler instances running in AWS can be deployed as standalone instances or in HA pairs.

The NetScaler VPX AMI is packaged as an EC2 instance that is launched within an AWS VPC. The VPX AMI instance requires a minimum of 2 virtual CPUs and 2 GB of memory. An EC2 instance launched within an AWS VPC can also provide the multiple interfaces, multiple IP addresses per interface, and public and private IP addresses needed for VPX configuration. Currently, on Amazon AWS, VPX can be launched only within a VPC, because each VPX instance requires at least three IP addresses. (Although VPX on AWS can be implemented with one or two elastic network interfaces, Citrix recommends three network interfaces for a standard VPX on AWS installation.) AWS currently makes multi-IP functionality available only to instances running within an AWS VPC. A VPX instance in a VPC can be used to load balance servers running in EC2 instances.

An Amazon VPC allows you to create and control a virtual networking environment, including your own IP address range, subnets, route tables, and network gateways.

Note: By default, you can create up to 5 VPC instances per AWS region for each AWS account. You can request higher VPC limits by submitting Amazon’s request form (http://aws.amazon.com/contact-us/vpc-request/).
An EC2 instance of NetScaler VPX (AMI image) is launched within the AWS VPC.

The following figure shows a typical VPX on AWS deployment.

The figure shows a simple topology of an AWS VPC with a NetScaler VPX deployment. The AWS VPC has:

1. A single Internet gateway to route traffic in and out of the VPC.
2. Network connectivity between the Internet gateway and the Internet.
3. Three subnets, one each for management, client, and server.
4. Network connectivity between the Internet gateway and the two subnets (management and client).
5. A single NetScaler VPX deployed within the VPC. The VPX instance has three Elastic Network Interfaces (ENIs), one attached to each subnet.

**Limitations and Usage Guidelines**

- The clustering feature is not supported for VPX.
- For HA to work as expected, associate a dedicated NATing device to management interface or associate EIP to NSIP. For more information on NAT, in the AWS documentation, see [NAT Instances](#).
- Data traffic and management traffic should be segregated by using ENIs belonging to different subnets.
- Only the NSIP address should be present on the management ENI.
• If a NAT instance is used for security instead of assigning an EIP to the NSIP, appropriate VPC level routing changes are required. For instructions on making VPC level routing changes, see "Scenario 2: VPC with Public and Private Subnets."

• A VPX instance can be moved from one EC2 instance type to another (for example, from m3.large to an m3.xlarge).

• For storage options for VPX on AWS, Citrix recommends EBS, because it is durable and the data is available even after it is detached from instance.

• Dynamic addition of ENIs to VPX is not supported. You have to restart the VPX instance to apply the update. Citrix recommends you to stop the standalone or HA instance, attach the new ENI, and then restart the instance.

• You can assign multiple IP addresses to an ENI. The maximum number of IP addresses per ENI is determined by the EC2 instance type, see EC2 Support for ENIs and IP Addresses.

• Citrix recommends that you avoid using the enable and disable interface commands on NetScaler VPX interfaces.

Due to Amazon AWS limitations, these features are not supported:

Layer 3 Limitations:
  • Dynamic Routing
  • IPv6

Layer 2 Limitations:
  • Gratuitous ARP (GARP)
  • L2 mode
  • Tagged VLAN
  • Virtual MAC (VMAC)

Supported EC2 instances

The NetScaler AMI can be launched on any of the following EC2 instance types:

• m4.large
• m4.xlarge
• m4.2xlarge
• m4.4xlarge
• m4.10xlarge
• m3.large
• m3.xlarge
• m3.2xlarge

For more information about Amazon EC2 instances, see:

ENI Support

The following table lists the EC2 instance types and corresponding number of supported ENIs and number of private IP addresses per ENI.
Use Cases

Compared to alternative solutions that require each service to be deployed as a separate virtual appliance, NetScaler on AWS combines L4 load balancing, L7 traffic management, server offload, application acceleration, application security and other essential application delivery capabilities in a single VPX instance, conveniently available via the AWS Marketplace. Furthermore, everything is governed by a single policy framework and managed with the same, powerful set of tools used to administer on-premise NetScaler deployments. The net result is that NetScaler on AWS enables several compelling use cases that not only support the immediate needs of today’s enterprises, but also the ongoing evolution from legacy computing infrastructures to enterprise cloud datacenters.

Production Delivery for Web and XenDesktop Applications

Enterprises actively embracing AWS as an infrastructure-as-a-service (IaaS) offering for production delivery of applications can now front-end those applications with the same cloud networking platform used by the largest websites and cloud service providers in the world. Extensive offload, acceleration and security capabilities can be leveraged to enhance performance and reduce costs.

XenDesktop 7.5 and XenApp 7.5 have been redesigned as cloud ready solutions for delivering any Windows application or desktop into a cloud service delivered across any network, to any device. By deploying this expanded app and desktop delivery platform today, you will be positioned to leverage any virtual infrastructure or cloud management platform giving you the ability to take advantage of the automation and orchestration capabilities of cloud computing.

Hybrid Cloud Designs

Enterprise IT organizations that follow a hybrid cloud strategy get the best of both worlds by selecting which applications and which usage scenarios fit best in their private cloud and which fit best in a public cloud enabling them to flex, grow and transform to meet the demands of the modern workplace.

With NetScaler on AWS, hybrid clouds that span enterprise datacenters and extend into AWS can benefit from the same NetScaler cloud networking platform, significantly easing the transition of applications and workloads back and forth between a private datacenter and AWS. The full suite of NetScaler capabilities, ranging from intelligent database load balancing with DataStream to unprecedented application visibility with AppFlow® and real-time monitoring and response with Action Analytics, can be leveraged with NetScaler on AWS.
Business Continuity

Enterprises looking to use AWS as part of their disaster recovery and business continuity plans can rely upon NetScaler global server load balancing running both on-premise and within AWS to continuously monitor availability and performance of both enterprise datacenters and AWS environments, ensuring users are always sent to the optimal location.

When you configure GSLB on NetScaler appliances and enable Metric Exchange Protocol (MEP), the appliances use the DNS infrastructure to connect the client to the data center that best meets the criteria that you set. The criteria can designate the least loaded data center, the closest data center, the data center that responds most quickly to requests from the client’s location, a combination of those metrics, and SNMP metrics. An appliance keeps track of the location, performance, load, and availability of each data center and uses these factors to select the data center to which to send a client request.

A GSLB configuration consists of a group of GSLB entities on each appliance in the configuration. These entities include GSLB sites, GSLB services, GSLB virtual servers, load balancing and/or content switching servers, and ADNS services.

Development and Testing

Enterprises running production delivery on-premise but using AWS for development and testing can now include NetScaler within their AWS test environments, speeding time-to-production due to better mimicry of the production implementation within their test environments.

In each use case, network architects can also leverage Citrix CloudBridge— configured either as a stand-alone instance or as feature of a NetScaler platinum edition instance—to secure and optimize the connection between the enterprise datacenter(s) and the AWS Cloud, thereby speeding data transfer/synchronization and minimizing network cost.

AWS Network Architecture – ENI and EIP

NetScaler instances launched into a VPC can have up to eight elastic network interfaces (ENIs). In turn, each ENI can be assigned one or more private IP addresses, with each of these optionally being mapped to an elastic IP address that is publicly routable.

What makes the network interfaces and IP addresses “elastic” in this case is the ability to programmatically re-map them to other instances—a feature that enables recovery from instance or Availability Zone failures without having to wait for hardware replacements, or for DNS changes to fully propagate to all of your customers.

Other details to account for include the following:

- An instance can have different ENIs in different subnets (but not in different Availability Zones).
- Each ENI must have at least one IP address assigned to it, and must be assigned to a Security Group (see below).
- Addresses 1 to 4 for each subnet (i.e., 10.x.x.1-4) are reserved for use by Amazon.
- NetScaler is only aware of private IP addresses. Any EIPs that are assigned will not show up within the NetScaler CLI or any related management tools.
EC2 versus VPC

AWS encompasses multiple different services, such as Amazon Simple Storage Services (S3), Amazon Elastic Compute Cloud (EC2), and Amazon Virtual Private Cloud (VPC). The distinction between the latter two is important in this case. In particular, with EC2, virtual machine instances are limited to a single networking interface and single IP address. Furthermore, there are minimal networking features and controls. This precludes the use of EC2 for NetScaler—which requires a minimum of three IP addresses—and is why NetScaler instances can only be launched within an AWS VPC.

VPCs not only support virtual machines with multiple interfaces and multiple private and public IP addresses, but also allow you to create and control an isolated virtual networking environment, with its own IP address range, subnets, routing tables and network gateways.

Regions and Availability Zones

Within the AWS Cloud, Regions refer to a specific geographic location, such as US East. Within each Region there are at least two Availability Zones, each of which can be thought of as an independent cloud datacenter that has been engineered to be insulated from failures in other Availability Zones and to provide inexpensive, low-latency network connectivity to other Availability Zones within the same Region.

By implementing instances in separate Availability Zones, you can protect your applications from failures that impact a single location.

Limitations and dependencies for network architects to be aware of at this level include the following:

- Although a Virtual Private Cloud can span multiple Availability Zones, it cannot span multiple Regions.
- Individual subnets within a VPC cannot span multiple Availability Zones.
- All traffic entering or leaving a VPC must be routed via a corresponding default Internet gateway.
Section 1: Configure VPX on AWS

In this exercise, you’ll create a VPC and subnet, and launch a public-facing instance into your subnet. Your instance will be able to communicate with the Internet, and you’ll be able to access your instance from your local computer using SSH (if it’s a Linux instance) or Remote Desktop (if it’s a Windows instance). In your real world environment, you can use this scenario to create a public-facing web server; for example, to host a blog.

Note:
This exercise is intended to help you set up your own nondefault VPC quickly. If you already have a default VPC and you want to get started launching instances into it (and not creating or configuring a new VPC), see Launching an EC2 Instance into Your Default VPC.

To complete this exercise, you’ll do the following:
- Create a nondefault VPC with a single public subnet. Subnets enable you to group instances based on your security and operational needs. A public subnet is a subnet that has access to the Internet through an Internet gateway.
- Create a security group for your instance that allows traffic only through specific ports.
- Launch an Amazon EC2 instance into your subnet.
- Associate an Elastic IP address with your instance. This allows your instance to access the Internet.

Before you can use Amazon VPC for the first time, you must sign up for Amazon Web Services (AWS). When you sign up, your AWS account is automatically signed up for all services in AWS, including Amazon VPC. If you haven’t created an AWS account already, go to http://aws.amazon.com, and then choose Create a Free Account.

Step 1: Create the VPC

In this step, you’ll use the Amazon VPC wizard in the Amazon VPC console to create a VPC. The wizard performs the following steps for you:
- Creates a VPC with a /16 CIDR block (a network with 65,536 private IP addresses). For more information about CIDR notation and the sizing of a VPC, see Your VPC.
- Attaches an Internet gateway to the VPC. For more information about Internet gateways, see Internet Gateways.
- Creates a size /24 subnet (a range of 256 private IP addresses) in the VPC.
- Creates a custom route table, and associates it with your subnet, so that traffic can flow between the subnet and the Internet gateway. For more information about route tables, see Route Tables.

The following diagram represents the architecture of your VPC after you’ve completed this step.
Create a VPC using the Amazon VPC Wizard

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation bar, on the top-right, take note of the region in which you’ll be creating the VPC. Ensure that you continue working in the same region for the rest of this exercise, as you cannot launch an instance into your VPC from a different region. For more information about regions, see Regions and Availability Zones.
3. In the navigation pane, choose VPC dashboard, and then choose Start VPC Wizard.

   ![VPC Dashboard](image)

   Note:
   Do not choose Your VPCs in the navigation pane; you cannot access the VPC wizard from this page.

4. Choose the first option, VPC with a Single Public Subnet, and then choose Select.
5. On the configuration page, enter a name for your VPC in the VPC name field; for example, my-vpc, and enter a name for your subnet in the Subnet name field. This helps you to identify the VPC and
subnet in the Amazon VPC console after you’ve created them. For this exercise, you can leave the rest of the configuration settings on the page, and choose Create VPC.

(Optional) If you prefer, you can modify the configuration settings as follows, and then choose Create VPC.

- The **IP CIDR block** displays the IP address range that you’ll use for your VPC (10.0.0.0/16), and the **Public subnet** field displays the IP address range you’ll use for the subnet (10.0.0.0/24). If you don’t want to use the default CIDR ranges, you can specify your own. For more information, see **VPC and Subnet Sizing**.
- The **Availability Zone** list enables you to select the Availability Zone in which to create the subnet. You can leave **No Preference** to let AWS choose an Availability Zone for you. For more information, see **Regions and Availability Zones**.
- In the **Add endpoints for S3 to your subnets** section, you can select a subnet in which to create a VPC endpoint to Amazon S3 in the same region. For more information, see **VPC Endpoints**.
- The **Enable DNS hostnames** option, when set to **Yes**, ensures that instances that are launched into your VPC receive a DNS hostname. For more information, see **Using DNS with Your VPC**.
- The **Hardware tenancy** option enables you to select whether instances launched into your VPC are run on shared or dedicated hardware. Selecting a dedicated tenancy incurs additional costs. For more information about hardware tenancy, see **Dedicated Instances**.

6. A status window shows the work in progress. When the work completes, choose **OK** to close the status window.

7. The **Your VPCs** page displays your default VPC and the VPC that you just created. The VPC that you created is a nondefault VPC, therefore the Default VPC column displays **No**.

Viewing Information About Your VPC

After you’ve created the VPC, you can view information about the subnet, the Internet gateway, and the route tables. The VPC that you created has two route tables — a main route table that all VPCs have by default, and a custom route table that was created by the wizard. The custom route table is associated with your subnet, which means that the routes in that table determine how the traffic for the subnet flows. If you add a new subnet to your VPC, it uses the main route table by default.

**To view information about your VPC**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Your VPCs**. Take note of the name and the ID of the VPC that you created (look in the **Name** and **VPC ID** columns). You will use this information to identify the components that are associated with your VPC.
3. In the navigation pane, choose **Subnets**. The console displays the subnet that was created when you created your VPC. You can identify the subnet by its name in **Name** column, or you can use the VPC information that you obtained in the previous step and look in the **VPC** column.

4. In the navigation pane, choose **Internet Gateways**. You can find the Internet gateway that's attached to your VPC by looking at the **VPC** column, which displays the ID and the name (if applicable) of the VPC.

5. In the navigation pane, choose **Route Tables**. There are two route tables associated with the VPC. Select the custom route table (the **Main** column displays **No**), and then choose the **Routes** tab to display the route information in the details pane:
   - The first row in the table is the local route, which enables instances within the VPC to communicate. This route is present in every route table by default, and you can't remove it.
   - The second row shows the route that the Amazon VPC wizard added to enable traffic destined for an IP address outside the VPC (0.0.0.0/0) to flow from the subnet to the Internet gateway.

6. Select the main route table. The main route table has a local route, but no other routes.

**Step 2: Create a Security Group**

A security group acts as a virtual firewall to control the traffic for its associated instances. To use a security group, you add the inbound rules to control incoming traffic to the instance, and outbound rules to control the outgoing traffic from your instance. To associate a security group with an instance, you specify the security group when you launch the instance. If you add and remove rules from the security group, we apply those changes to the instances associated with the security group automatically.

Your VPC comes with a *default security group*. Any instance not associated with another security group during launch is associated with the default security group. In this exercise, you'll create a new security group, **WebServerSG**, and specify this security group when you launch an instance into your VPC.

**Topics**

- Creating Your **WebServerSG** Security Group
- Rules for the **WebServerSG** Security Group

**Creating Your WebServerSG Security Group**

You can create your security group using the Amazon VPC console.

**Rules for the WebServerSG Security Group**

The following table describes the inbound and outbound rules for the WebServerSG security group. You'll add the inbound rules yourself. The outbound rule is a default rule that allows all outbound communication to anywhere — you do not need to add this rule yourself.
To create the WebServerSG security group and add rules

1. Open the Amazon VPC console at [https://aws.amazon.com/console/](https://aws.amazon.com/console/).
2. In the navigation pane, choose Security Groups.
4. In the Group name field, enter WebServerSG as the name of the security group, and provide a description. You can optionally use the Name tag field to create a tag for the security group with a key of Name and a value that you specify.
5. Select the ID of your VPC from the VPC menu, and then choose Yes, Create.
6. Select the WebServerSG security group that you just created (you can view its name in the Group Name column).
7. On the Inbound Rules tab, choose Edit and add rules for inbound traffic as follows, and then choose Save when you’re done:
   a. Select HTTP from the Type list, and enter 0.0.0.0/0 in the Source field.
   b. Choose Add another rule, then select HTTPS from the Type list, and enter 0.0.0.0/0 in the Source field.
   c. Choose Add another rule. If you’re launching a Linux instance, select SSH from the Type list, or if you’re launching a Windows instance, select RDP from the Type list. Enter your network’s public IP address range in the Source field. If you don’t know this address range, you can use 0.0.0.0/0 for this exercise.

Caution:

If you use 0.0.0.0/0, you enable all IP addresses to access your instance using SSH or RDP. This is acceptable for the short exercise, but it’s unsafe for production environments. In production, you’ll authorize only a specific IP address or range of addresses to access your instance.

Step 3: Launch an Instance into Your VPC

When you launch an EC2 instance into a VPC, you must specify the subnet in which to launch the instance. In this case, you’ll launch an instance into the public subnet of the VPC you created. You’ll use the Amazon EC2 launch wizard in the Amazon EC2 console to launch your instance.

The following diagram represents the architecture of your VPC after you’ve completed this step.

To launch an EC2 instance into a VPC

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar, on the top-right, ensure that you select the same region in which you created your VPC and security group.
3. From the dashboard, choose Launch Instance.
4. On the first page of the wizard, choose the AMI that you want to use. For this exercise, we recommend that you choose an Amazon Linux AMI or a Windows AMI.
5. On the Choose an Instance Type page, you can select the hardware configuration and size of the instance to launch. By default, the wizard selects the first available instance type based on the AMI you selected. You can leave the default selection, and then choose Next: Configure Instance Details.
6. On the Configure Instance Details page, select the VPC that you created from the Network list, and the subnet from the Subnet list. Leave the rest of the default settings, and go through the next pages of the wizard until you get to the Tag Instance page.
7. On the **Tag Instance** page, you can tag your instance with a Name tag; for example, Name=MyWebServer. This helps you to identify your instance in the Amazon EC2 console after you’ve launched it. Choose **Next: Configure Security Group** when you are done.

8. On the **Configure Security Group** page, the wizard automatically defines the launch-wizard-x security group to allow you to connect to your instance. Instead, choose the **Select an existing security group** option, select the **WebServerSG** group that you created previously, and then choose **Review and Launch**.

9. On the **Review Instance Launch** page, check the details of your instance, and then choose **Launch**.

10. In the **Select an existing key pair or create a new key pair** dialog box, you can choose an existing key pair, or create a new one. If you create a new key pair, ensure that you download the file and store it in a secure location. You’ll need the contents of the private key to connect to your instance after it’s launched. To launch your instance, select the acknowledgment check box, and then choose **Launch Instances**.

11. On the confirmation page, choose **View Instances** to view your instance on the **Instances** page. Select your instance, and view its details in the Description tab. The **Private IPs** field displays the private IP address that’s assigned to your instance from the range of IP addresses in your subnet.

**Step 4: Assign an Elastic IP Address to Your Instance**

In the previous step, you launched your instance into a public subnet — a subnet that has a route to an Internet gateway. However, the instance in your subnet also needs a public IP address to be able to communicate with the Internet. By default, an instance in a nondefault VPC is not assigned a public IP address. In this step, you’ll allocate an Elastic IP address to your account, and then associate it with your instance. For more information about Elastic IP addresses, see [Elastic IP Addresses](#).

The following diagram represents the architecture of your VPC after you’ve completed this step.
To allocate and assign an Elastic IP address

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Elastic IPs.
3. Choose Allocate New Address, and then Yes, Allocate.

Note
If your account supports EC2-Classic, first select EC2-VPC from the Network platform list.

4. Select the Elastic IP address from the list, choose Actions, and then choose Associate Address.
5. In the dialog box, choose Instance from the Associate with list, and then select your instance from the Instance list. Choose Yes, Associate when you’re done.

Your instance is now accessible from the Internet. You can connect to your instance through its Elastic IP address using SSH or Remote Desktop from your home network. For more information about how to connect to a Linux instance, see Connecting to Your Linux Instance in the Amazon EC2 User Guide for Linux Instances. For more information about how to connect to a Windows instance, see Connect to Your Windows Instance Using RDP in the Amazon EC2 User Guide for Windows Instances.

This completes the exercise; you can choose to continue using your instance in your VPC, or if you do not need the instance, you can terminate it and release its Elastic IP address to avoid incurring charges for them. You can also delete your VPC — note that you are not charged for the VPC and VPC components created in this exercise (such as the subnets and route tables).

Section 2: Configure Unified Gateway for XenDesktop

Navigate to the admin console of your NetScaler.

Log into the NetScaler using nsroot and the Instance ID that Amazon AWS assigned during the build process.

Install SSL Certificate:

1. Navigate to Traffic Management – SSL. Right click and enable this feature.
2. Import SSL certificate an key pair.

Install SSL Certificate:

1. Expand NetScaler Gateway and select Virtual Servers.
2. Click Add.

Enter a name for the gateway and IP Address that is in the Public Subnet you assigned during the NetScaler Build process.

NOTE: Write down this IP Address as we will need it when allocating the Elastic IP Addresses later on.

3. Click on OK then click on “No Server Certificate” and select the certificate you imported earlier and click bind.
4. Click on OK and Done and at this stage you should have a NetScaler Gateway being shown in an “Up” state.
Configure the Unified Gateway:

Please refer to CTX Article:

https://support.citrix.com/article/CTX205485

Provide external access to the Unified Gateway Instance:

1. Login to your AWS Portal at aws.amazon.com and navigate to your instances.
2. Right click on your NetScaler, Select Networking and then Manage Private IP Addresses.
3. Click on Assign New IP on the interface you want to run the NetScaler Gateway on.
4. Assign the IP Address make sure you use the SAME address that you assigned to your NetScaler Gateway.
5. Click on “Yes Update”. This will assign the new IP Address to the instance at an AWS level. You can now assign a new Elastic IP to this Private IP.
6. Navigate to Network and Security and Elastic IP’s,
7. Click “Allocate New Address”, when prompted – select Yes to get a new IP Address.
8. Select the address from the list and select Associate Address.
9. Select the NetScaler instance you built previously from the Instance List. Once this is selected you will be able to select the IP Address you statically assigned to the instance (the same address as your NetScaler Gateway) and select Associate.

10. Point your DNS name record to the elastic ip address Amazon assigned you.
11. Log into your NetScaler Gateway.

**Section 3: High Availability Load Balancing for Storefront**

Please refer to Citrix Configuration steps:

**Section 4: Configure GSLB in Two AWS locations**

Setting up GSLB for NetScaler on AWS largely consists of configuring the NetScaler to load balance traffic to servers located outside the VPC that the NetScaler belongs to, such as within another VPC in a different Availability Region or an on-premise datacenter etc.

Cloud Networking and Desktop Virtualization Solutions for Amazon Web Services
About Citrix

Citrix (NASDAQ: CTXS) is a leader in mobile workspaces, providing virtualization, mobility management, networking and cloud services to enable new ways to work better. Citrix solutions power business mobility through secure, personal workspaces that provide people with instant access to apps, desktops, data and communications on any device, over any network and cloud. This year Citrix is celebrating 25 years of innovation, making IT simpler and people more productive. With annual revenue in 2013 of $2.9 billion, Citrix solutions are in use at more than 330,000 organizations and by over 100 million users globally. Learn more at www.citrix.com.
