Finding the Best SD-WAN Product for Your Enterprise: Criteria for Evaluating Software-Defined WAN Products

Selecting the optimal SD-WAN solution for your enterprise is not easy. With vendors and industry analysts all talking about the same topics using the same buzzwords, it’s hard to decide what features are most important, and how to differentiate between products. This paper lays out some important factors to consider when selecting an SD-WAN solution.

SD-WAN (Software Defined Wide Area Network) products have a very successful track record improving application performance, lowering WAN costs, and strengthening business continuity. But as you consider deploying SD-WAN, it’s important to understand the differences between solutions. Identifying which features matter to your enterprise is essential in making this selection.

This paper describes key criteria for evaluating SD-WAN solutions. It discusses the most important issues, and outlines levels of capability that separate “just okay” products from really good ones. The paper does not compare specific products, but it does include examples of features from Citrix NetScaler SD-WAN, one of the leading solutions in this field.

The Value of SD-WAN Solutions

Wide Area Networks are a critical component of today’s enterprise computing infrastructure. But WANs suffer from many problems, including congestion, jitter, packet loss, and outages. Erratic performance frustrates users, especially for low-latency applications like VoIP calling, video conferencing, video streaming, and virtualized applications and desktops. WAN capacity can be expensive and difficult to expand. Complex WANs are difficult to manage and troubleshoot.

SD-WAN products address these problems. Typically they are appliances or virtual appliances placed in small remote and branch offices, larger offices, corporate data centers, and increasingly on cloud platforms. SD-WAN solutions can:

• Reduce WAN traffic
• Route traffic on the fastest available paths between any two points
• Provide better quality of service (QoS) for high-priority applications
• Improve network security
• Simplify administration for remote and branch offices
• Allow enterprises to leverage low-cost and flexible Internet and 4GE network connections in place of MPLS links.
• Provide visibility into WAN paths to help administrators troubleshoot performance issues

The Difference is in the Details

Although most SD-WAN products address the same problems, they provide very different levels of capability. Enterprises evaluating SD-WAN solutions should understand the different levels of functionality available to solve different problems, determine what level they require, and look for products that offer those capabilities.
Resiliency and Failover

The failure of a network link can put users “out of business.” Losing access to mission-critical applications can reduce productivity and affect customer service. Manually rerouting traffic to back-up links forces high-priority applications to contend with all other traffic for limited bandwidth, creating even more user dissatisfaction. SD-WAN products are essential tools for improving resiliency and providing fast failover.

Reliable Packet Delivery

SD-WAN solutions make packet delivery and application performance more reliable by routing network traffic along the optimal paths between two points, based on factors like the requirements and priority of the application and the capacity and quality of the available paths.

A few SD-WAN offerings rely on administrators to pre-define paths for all applications, and to make manual adjustments when contention and low quality are detected on a path. Most SD-WAN products, however, automatically assign paths based on factors such as latency (i.e., the time required for a ping to make a round trip between the locations). The highest-priority applications are re-assigned to the lowest-latency paths.

Problems can still arise, however, when the selection criteria are too narrow, when thresholds are set too high or too low, or when it takes the product more than a few seconds to detect that the path has deteriorated or failed.

More sophisticated SD-WAN solutions select paths using algorithms based on multiple factors such as packet loss, jitter, and congestion as well as latency. These solutions use a dynamic analysis of multiple criteria, rather than fixed thresholds, to determine when paths need to be changed. The highest-priority applications are re-assigned to the lowest-latency paths. These capabilities do a better job of matching high-priority applications with the highest quality paths, and of making adjustments faster when path quality deteriorates.

Real-time Detection of Outages

When a network link goes down, lost connectivity can interfere with critical business processes and anger users. Even a short interruption can cause users to hang up on a VoIP call or teleconference and to restart applications. It can also disrupt virtual desktop sessions, backups, large file transfers, and other key software activities.

SD-WAN solutions can detect outages of network links and reroute traffic to alternate paths. The best products can identify outages and take corrective actions in a second or less, making the outages imperceptible to users (see the Sub-second Detection of Path Outages callout box).

Dynamic Path Selection for Failover

When a path outage is detected, some SD-WAN products redirect traffic to a pre-defined backup link. More sophisticated solutions intelligently reroute traffic from high-priority applications to the remaining paths with the best performance and the lowest packet loss and jitter, and traffic from lower priority applications to the next-best path with available capacity. This ensures that high-priority applications not only continue to function, but in most cases suffer no performance degradation.

Quality of Service

Not all applications need the same levels of service from the network. Some applications require high performance, high reliability, and high quality in order to deliver the expected user experience. For example, many users will get very angry if quality is erratic for voice over IP (VoIP calling), audio and video streaming, or if performance deteriorates for virtualized applications and desktops. In these situations, poor quality can cause users to stop and restart the phone call, the download, or the virtualized application, making network performance even worse. But what features in SD-WAN solutions can guaranty excellent QoS for key applications?
Application Prioritization
Most SD-WAN products allow administrators to assign applications to a series of categories that range from “high priority” to “low priority,” or from “real-time” to “bulk.”

More sophisticated solutions allow administrators to prioritize applications at an even more granular level by creating rules based on parameters such as the application, the user, the protocol, and source and destination IP addresses.

Traffic Shaping and Bandwidth Reservation
Some SD-WAN products include features for traffic shaping and dynamic bandwidth reservation. For example, a minimum bandwidth can be specified for a certain class of application on a given path. This feature ensures that no matter how congested a path becomes, no important application class will ever be forced below a minimum bandwidth allocation.

A refinement on this approach is to also specify a “share” for each class of application, so that when capacity is limited bandwidth will be allocated between them based on their relative shares.

Another traffic shaping technique is detecting “backpressure” from a destination. If the SD-WAN appliance at the destination indicates that there is no spare capacity, the appliance at the source will hold back traffic to that location, and use the resulting free bandwidth to send packets somewhere else. This promotes efficient use of overall bandwidth while preventing the destination from being even more overloaded.

Packet Duplication
An advanced SD-WAN solution can ensure high application performance and zero packet loss by sending duplicate packets from the source location to the destination via two independent paths. The first packet to reach the destination is used and the second is discarded. This approach uses some extra bandwidth, but it is a powerful tool for ensuring very high reliability and quality for applications like VoIP calling, video conferencing, and virtualized desktops.

Multiple Paths Per Session
Some advanced SD-WAN products allow traffic from a single session to be divided over two or more paths that are dynamically linked. This has two important benefits:

- Large tasks such as backups and large file transfers can be completed more quickly.
- High-priority applications can be given enough bandwidth to perform optimally, even if the primary path for the application reaches its capacity.

Dynamic Point-to-Point Connections
Applications like VoIP calling, video conferencing and chat often require connections between two remote points (say branch offices) that have to go through a corporate data center, or a cloud platform, or make multiple hops. When one of these applications starts a session, an advanced SD-WAN solution can create an on-demand connection that utilizes the shortest possible path and dynamically combines multiple links into a single virtual path. It can also apply features like dynamic path selection and traffic shaping end-to-end.

Application Optimization

Basic Compression and Caching
All SD-WAN products provide basic compression (removing unneeded and repetitive characters) and basic caching (storing copies of frequently used files at the destination node so they don’t have to be retrieved multiple times across the WAN). These capabilities improve application performance, which makes users happy, and decrease congestion on networks, which reduces networking costs.
Advanced Deduplication and Protocol Acceleration
Some SD-WAN solutions provide advanced techniques for application optimization on top of basic compression and caching.

Advanced deduplication includes the ability to cache and reuse individual blocks and bytes, in addition to entire file objects. A related feature is storing in memory small, frequently used data streams so they can be accessed extremely fast.

With protocol acceleration, details of specific protocols can be used to eliminate unnecessary actions that take up network capacity. Examples include proxying client-server handshakes, reducing protocol chattiness, and optimizing payloads (see the Accelerating CIFS callout box).

Application Fluency and Video Delivery Optimization
"Application fluency" refers to a technology that can parse application traffic and leverage knowledge about features in specific applications, rather than treating all application traffic as an undifferentiated stream. (See the Microsoft Apps and Virtualized Apps callout box.)

Video delivery can be optimized by identifying, classifying and caching video files based on video format, as well as by object-level compression of video files. This can result in major bandwidth savings and performance improvements when multiple people at the one location view the same video.

Security
Most SD-WAN solutions use IP-SEC encryption to protect data in motion.

Some include additional security features such as rotating keys, and splitting designated application traffic across multiple links so it can’t be understood even if a hacker can eavesdrop on one network segment.

A few SD-WAN products can also inspect SSL/TLS encrypted tunnels. This allows them to apply traffic shaping to traffic from Facebook, YouTube, Twitter, Google Apps, Box, Salesforce.com, GitHub, and the many other web applications that use SSL/TLS encryption.

Deployment Options and Scaling
Most SD-WAN solutions are available as pre-configured appliances. However, some vendors offer a choice of deployment options that includes pre-configured appliances (easy to deploy), virtual appliances that run on the enterprise’s existing hardware (low cost and easy to upgrade), and virtual appliances on cloud platforms (see the Cloud Deployment callout box).

SD-WAN solutions can also help enterprises scale their WANs very cost-effectively, by adding capacity with broadband and 4GE connections, rather than by investing in expensive additional MPLS circuits.

Administration and Troubleshooting
Some SD-WAN products need more effort to configure and manage. Administrators should be concerned about solutions that use command-line type commands for some activities, depend on manual selection of paths, or require configuration tasks on each individual appliance.

More advanced solutions provide an easy-to-use GUI interface, use algorithms to select paths automatically, and include tools to push out configuration changes quickly to multiple appliances. A few also implement a true "software defined networking" approach that allows all appliances and virtual appliances to be configured centrally based on application needs rather than underlying hardware.
Example: Analytics

NetScaler Insight Center collects data from NetScaler SD-WAN appliances and provides visibility into the behavior of over 200 enterprise applications. It can use industry-standard AppFlow® data reporting formats to feed data to third party analytics tools from organizations like Splunk and Solarwinds. The HDX Insight™ module within Insight Center can provide extremely detailed reporting and analysis of XenApp and XenDesktop activity, including application launches, bandwidth usage, response times and errors by application, by user group, and by individual user.

Administrators should also evaluate the analysis and troubleshooting tools that work with the SD-WAN solution. Desirable features include:

- A dashboard with useful charts, maps and diagrams.
- Visibility into the status, utilization and performance of individual network segments.
- Visibility into the end-to-end performance of a wide range of applications.
- Integration with third party analytics and troubleshooting tools.
- The ability to replay traffic flows over time and observe the effect of changes in application usage and network conditions.

Vendor Track Record and Support

SD-WAN technology is improving rapidly, and the vendor landscape is changing. To maximize their return on investment now and in the future, enterprises should look for vendors who have long-standing track records for industry leadership and customer satisfaction, as well as world-class support, sales, and channel organizations.

Conclusions

SD-WAN products have been proven to increase application performance and reliability and to dramatically reduce the costs of expanding and managing wide area networks. But SD-WAN solutions are not the same. Evaluators should weigh alternatives based on the features and levels of capabilities outlined in this paper in the areas of:

- Resiliency and failover
- Prioritization and Quality of Service
- Application optimization
- Security
- Deployment options and scaling
- Administration and troubleshooting
- Vendor track record and support

You can use the checklist on the next page to compare several products using these criteria. Of course, potential buyers should also validate the capabilities most important to them by looking at each vendor’s customer base and performing hands-on trials where appropriate.

Citrix invites you to explore how an advanced SD-WAN solution can address the business and technical requirements of your enterprise. For more information, visit www.citrix.com/sdwan, or read more in the following white papers:

**About Citrix**

Citrix (NASDAQ: CTXS) is leading the transition to software-defining the workplace, unifying virtualization, mobility management, networking and SaaS solutions to enable new ways for businesses and people to work better. Citrix solutions power business mobility through secure, mobile workspaces that provide people with instant access to apps, desktops, data and communications on any device, over any network and cloud. With annual revenue in 2014 of $3.14 billion, Citrix solutions are in use at more than 330,000 organizations and by over 100 million users globally. Learn more at www.citrix.com.
